

Which statistic of the proxy alone predicts decision accuracy?

point = Spearman ρ , over the tasks above chance at the proxy and at 1.7B where the statistic has a value (n next to it; ≥ 8), between the statistic read on the proxy and the task's DA-size (proxy final $\rightarrow$ 1.7B final); the R^2 is fitted on the rungs up to the proxy only; `bpb\_macro` and `train\_loss` are in neither population
